# Raw Lignin Modification and Waste Recovery for Tissue Adhesive Formulations

## Motivation

### Introduction

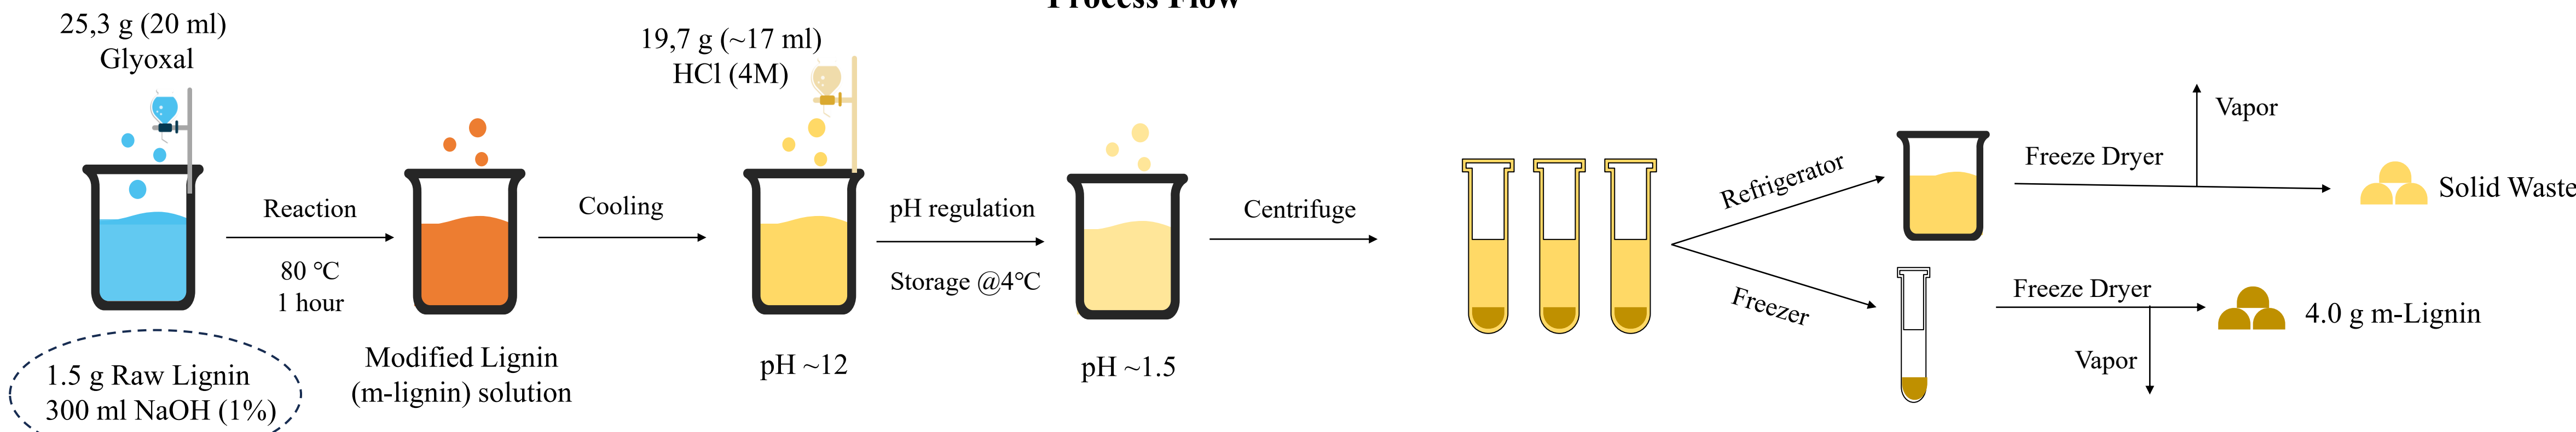

- Raw lignin has limited adhesive performance in its native form.
- Chemical modification is essential to improve its functionality.
- This study focuses on:
  - Improving lignin via glyoxal modification.
  - Reducing chemical use.
  - Exploring waste reuse strategies during precipitation.

### Objective

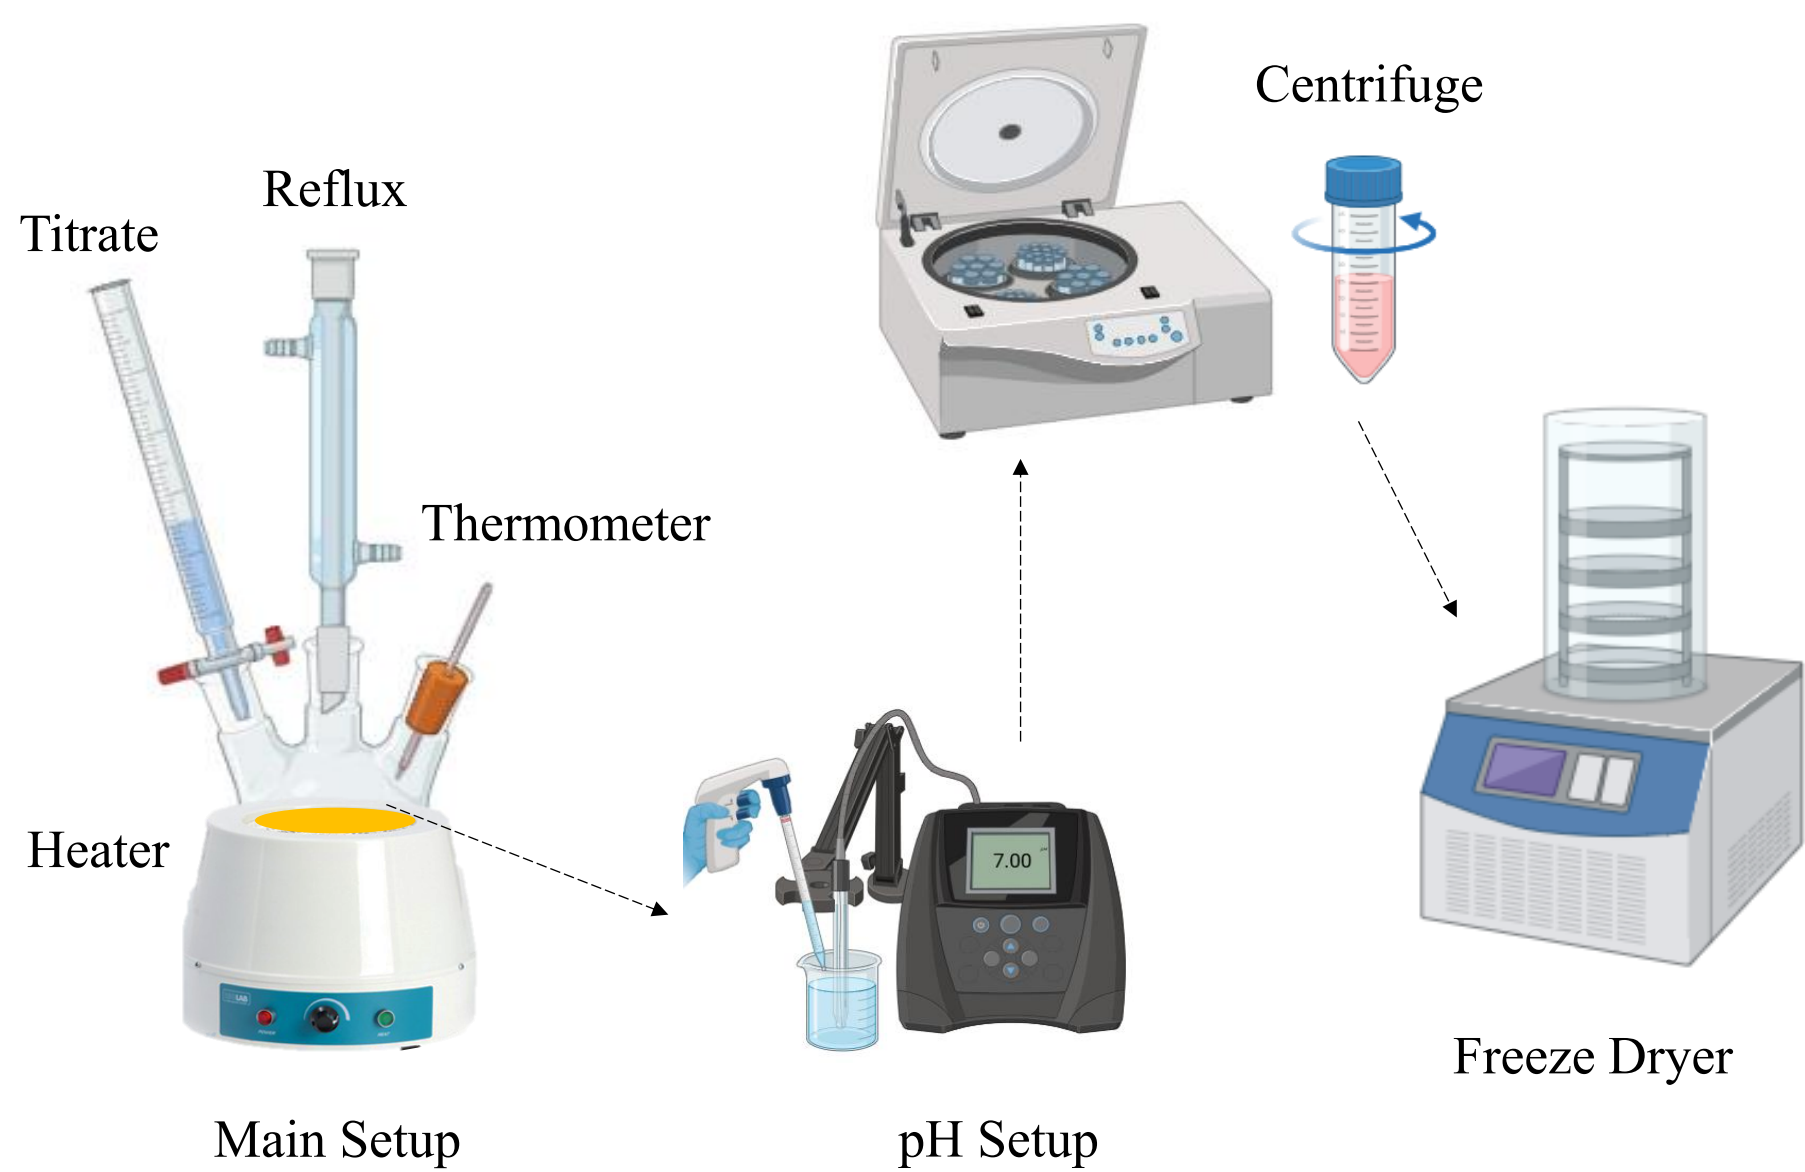

- Optimize glyoxal concentration in the modification process.
- Minimize consumption of chemicals.
- Reuse the acidic waste solution instead of fresh HCl.
- Evaluate the quality of lignin obtained from recycled systems.
- Establish a complete mass balance of the process.

## Material & Methods

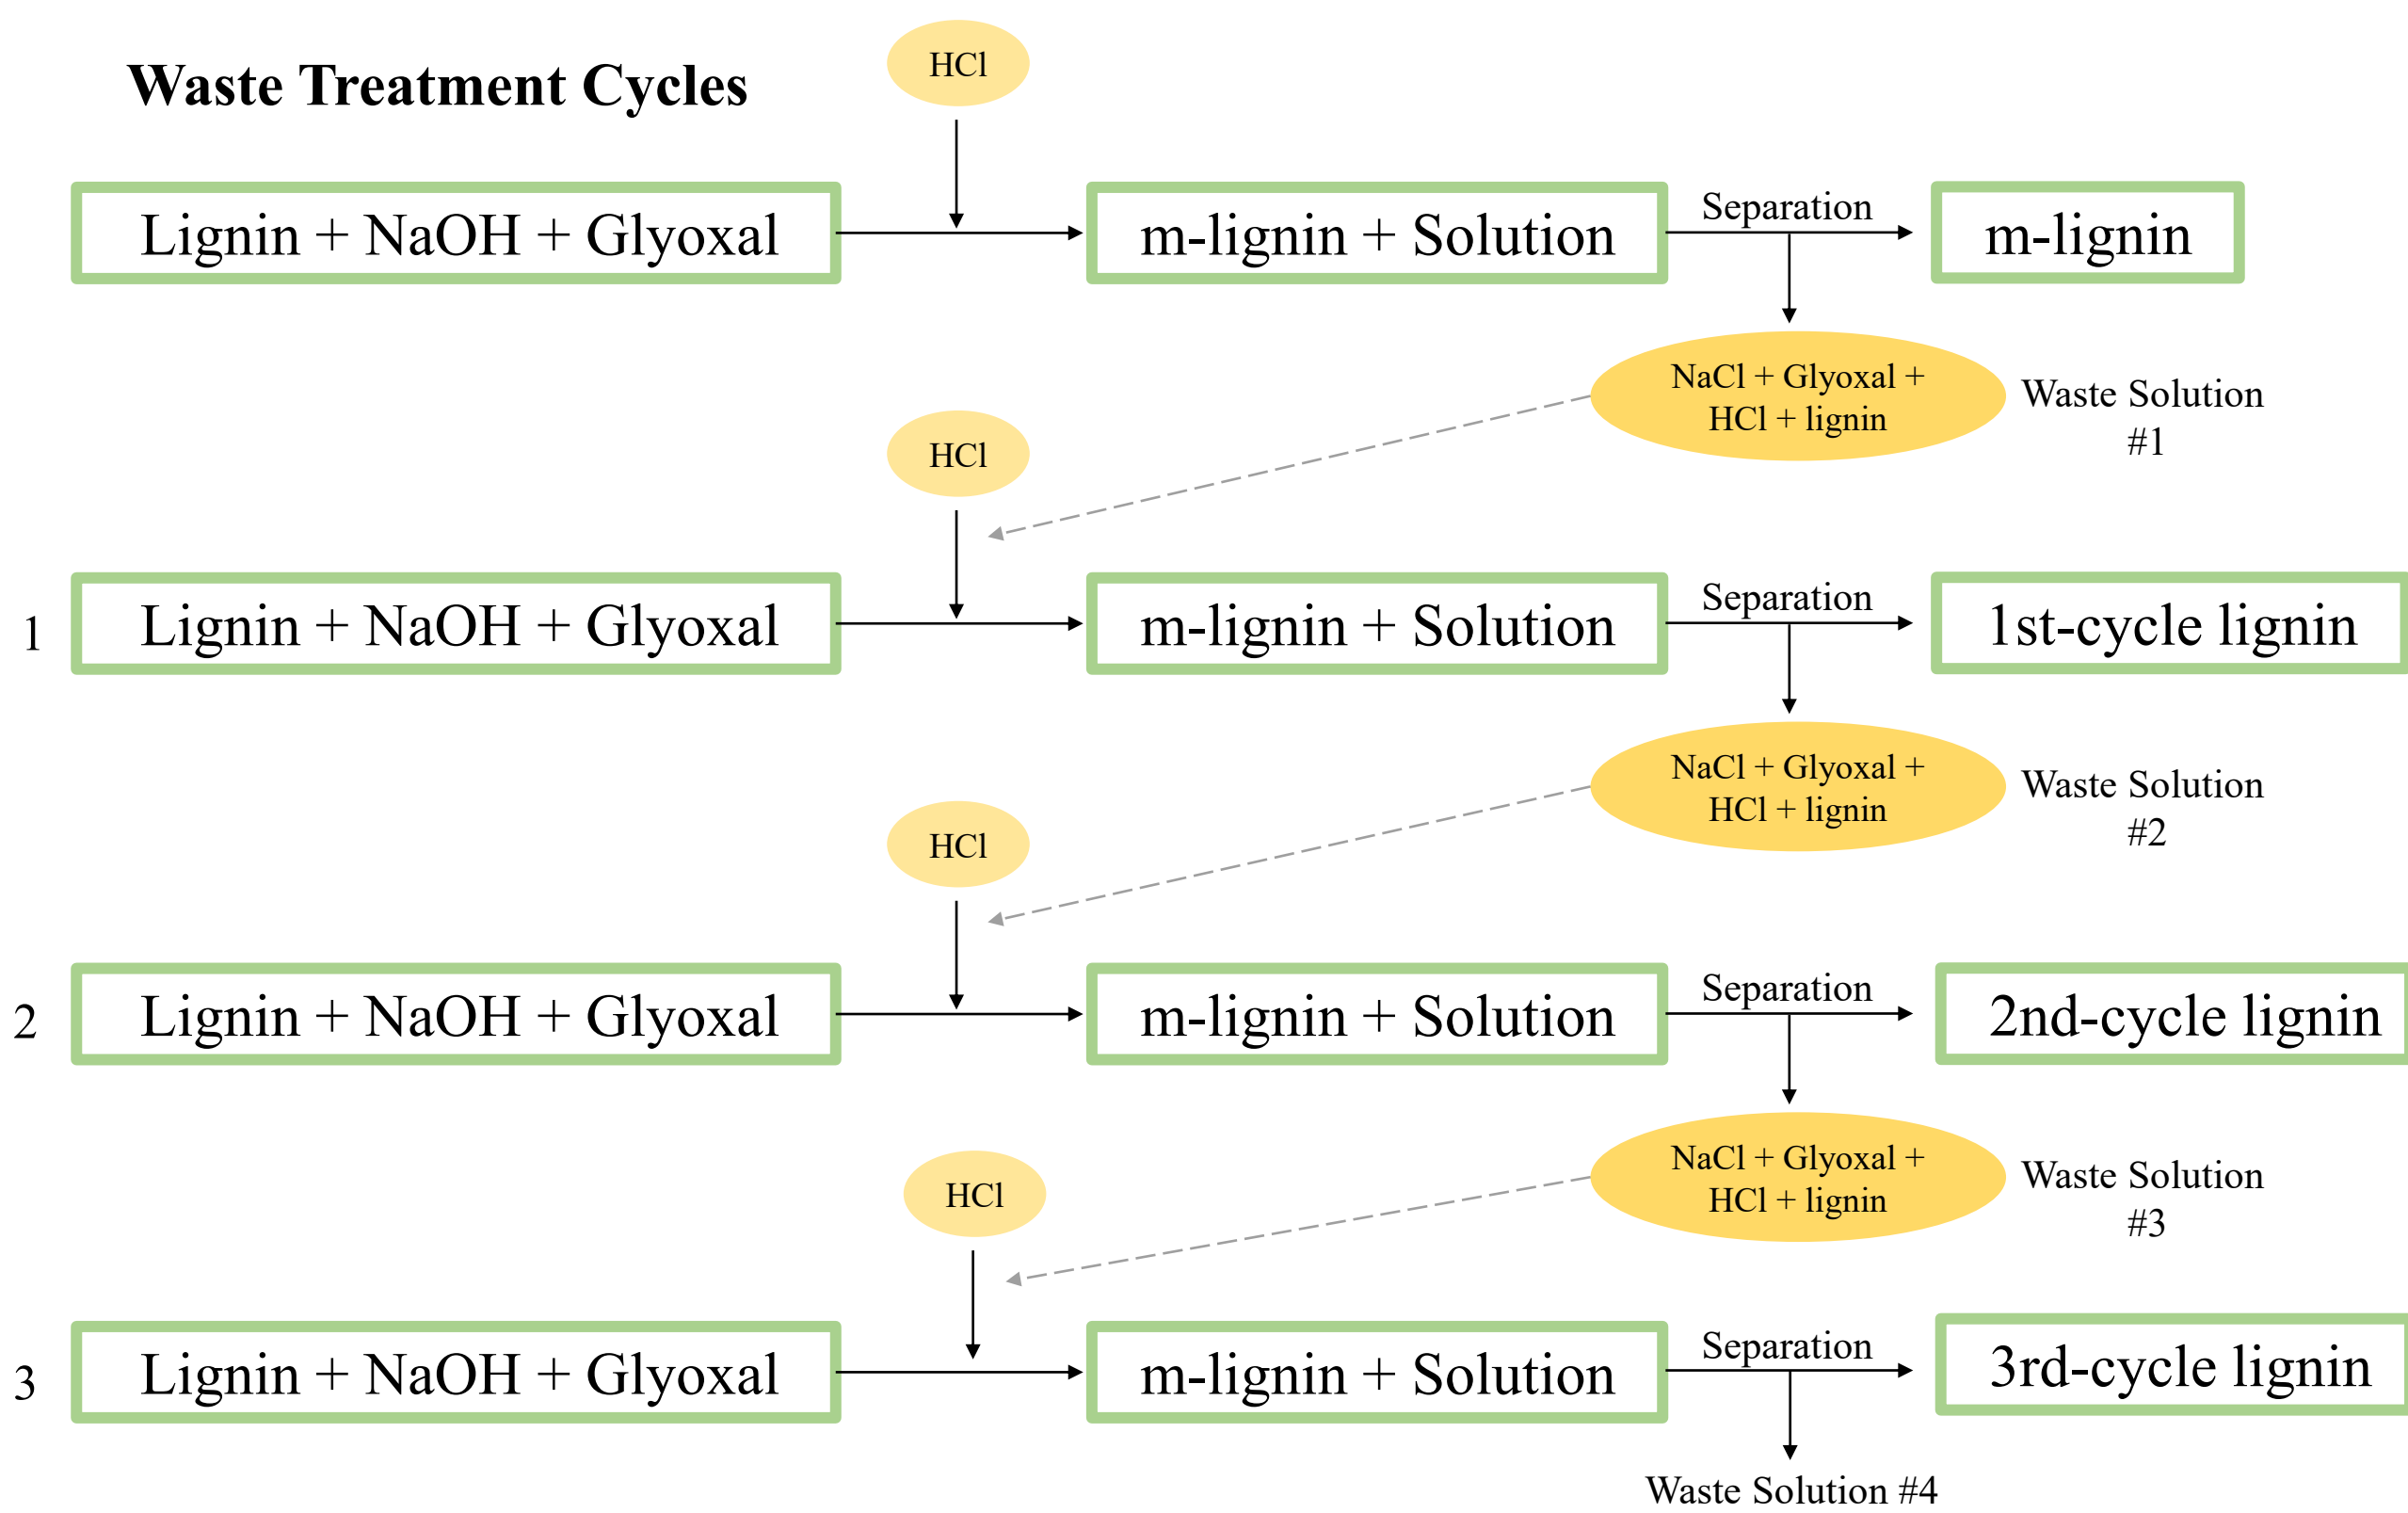

### Process Flow

### Experimental Setup

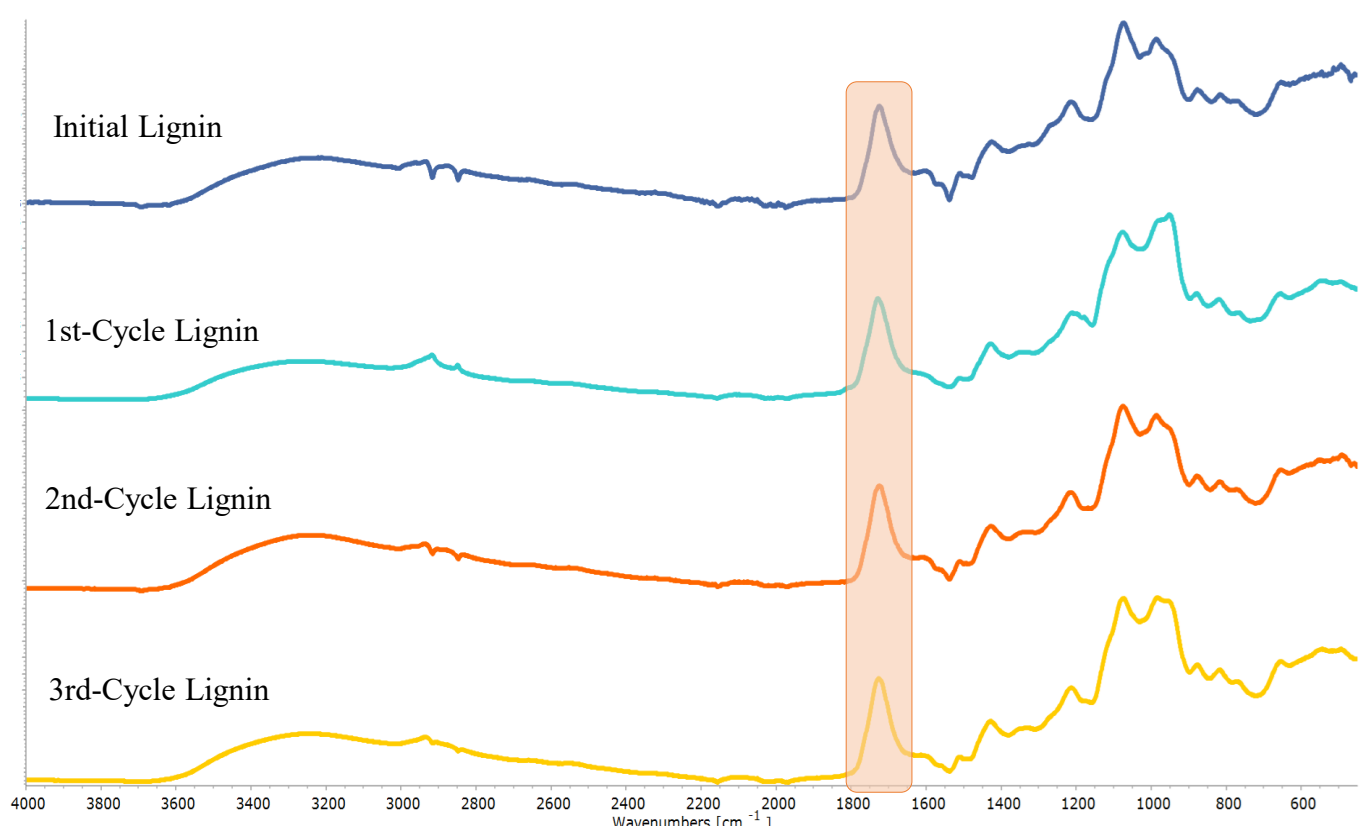

### Waste Treatment Cycles

## Results

### FTIR Analysis

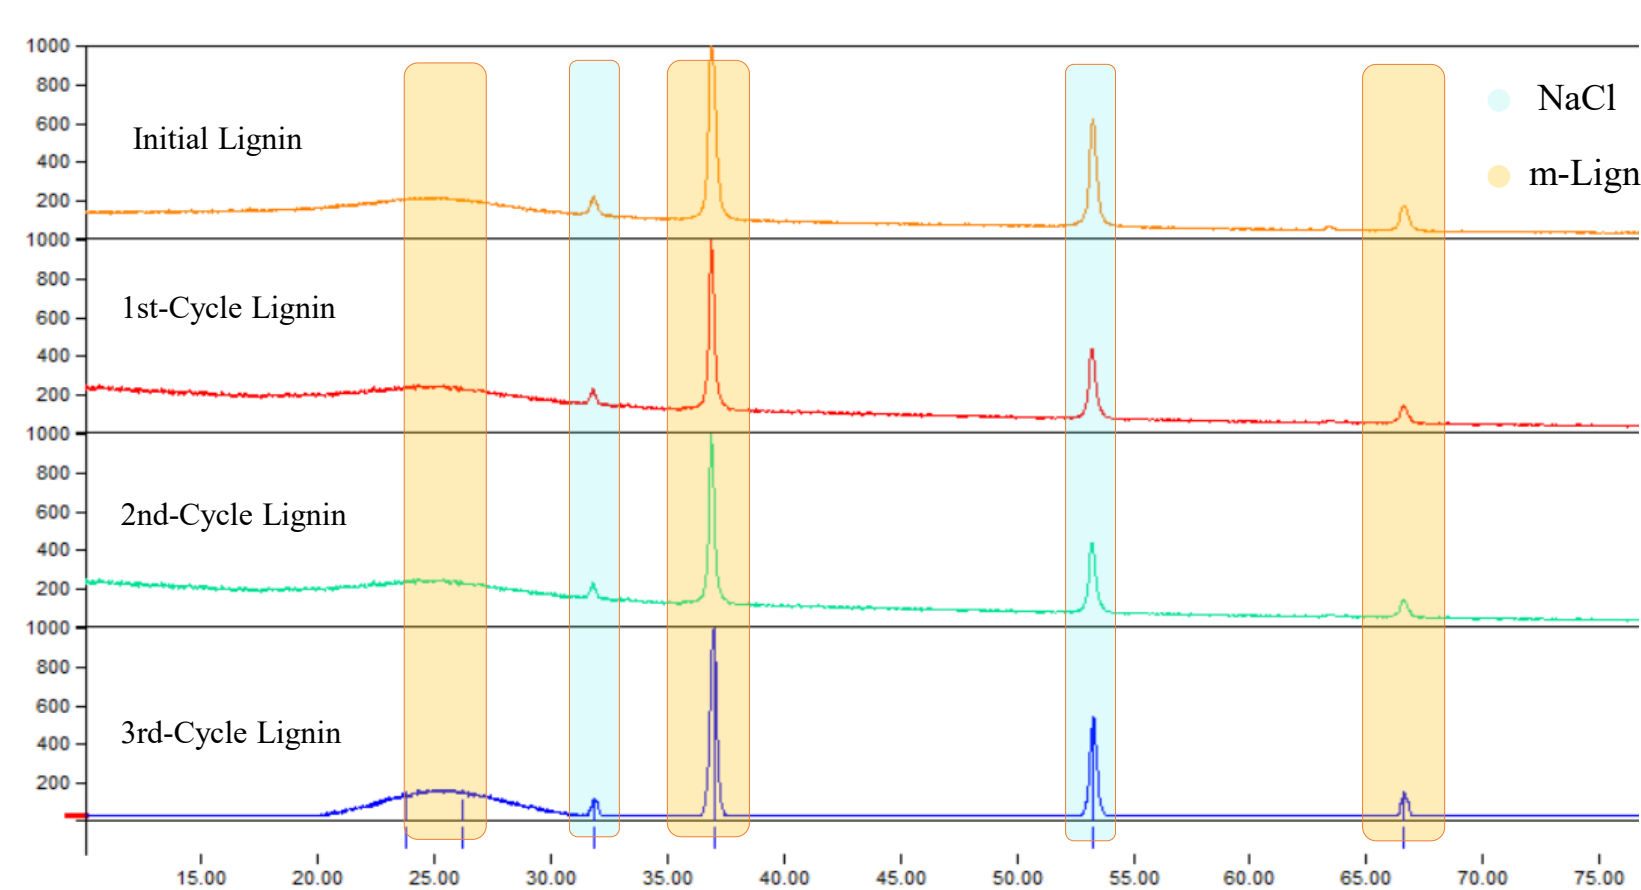

### m-Lignin Regaining

Cycle #	% Regaining
1	22.5
2	30
3	60

- Modified lignin quality was preserved across reuse cycles.
- Reuse of acidic waste successfully reduced fresh acid consumption.
- Process remained sustainable up to **24 cycles**, based on NaCl accumulation.
- **Total process loss <10%**, regaining of m-Lignin from waste is efficient.
- The approach supports environmental sustainability and cost reduction.

### XRD Analysis

### Fresh Acid Usage Reducing

Cycle #	% HCl Reduction
1	46.1
2	64.9
3	70.5

## Conclusion

### Conclusion

- Lignin can be effectively modified using glyoxal with minimal fresh chemical input.
- Reuse of acidic waste solution is feasible and efficient.
- The process provides a scalable and eco-friendly route for biopolymer development.
- Mass balance and m-lignin recovery support industrial application potential.

### Outlook

- Modified lignins obtained from each cycle will be used in tissue adhesive formulations. Adhesive performance will be evaluated through:
  - Tensile strength tests under dry and moist conditions, and
  - Rheological characterization of the formulations.
- To further reduce system accumulation, the waste stream will be treated by:
  - Eutectic Freeze Crystallization (EFC), enabling the simultaneous removal of water (as ice) and NaCl (as crystals) from the solution.
